Corporate Technology

Using KVM as a Real-Time Hypervisor

Jan Kiszka, Siemens AG, CT T DE IT 1
Corporate Competence Center Embedded Linux
jan.kiszka@siemens.com

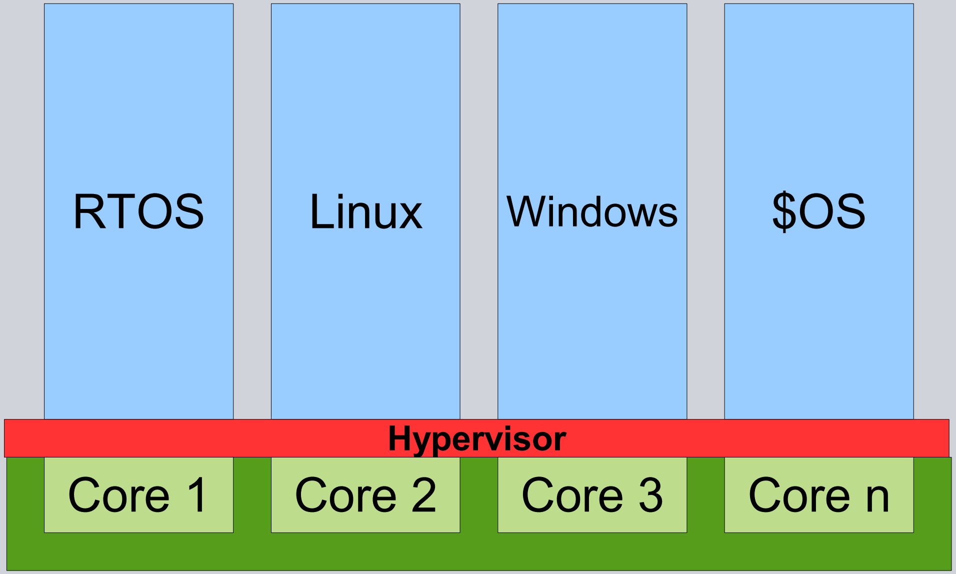
Agenda

- **Motivation & scenarios**
- **RT benchmark updates**
- **Improving QEMU RT performance**
  - Analysis of critical paths
  - Steps to overcome latency spots
- **Summary**

Recall Last Year: Why Using KVM in Embedded?

"We just need a tiny hypervisor to fully exploit this multicore CPU"

- "A few thousand" lines of hypervisor code
- Minimal hardware emulation
- "A bit" paravirtualization
- Devices are passed through



Recall Last Year: Why Using KVM in Embedded?

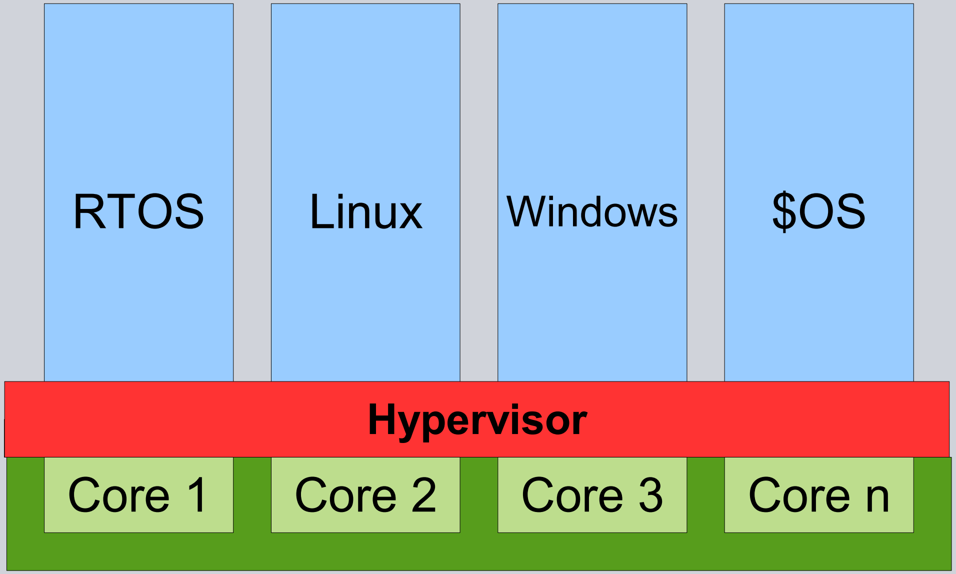
SIEMENS

“We just need a tiny hypervisor to fully exploit this multicore CPU”

- “A few thousand” lines of hypervisor code
- Minimal hardware emulation
- “A bit” paravirtualization
- Devices are passed through

“But it would be nice to...”

- share some devices
- run upstream Linux and latest Windows



Recall Last Year:
Why Using KVM in Embedded?

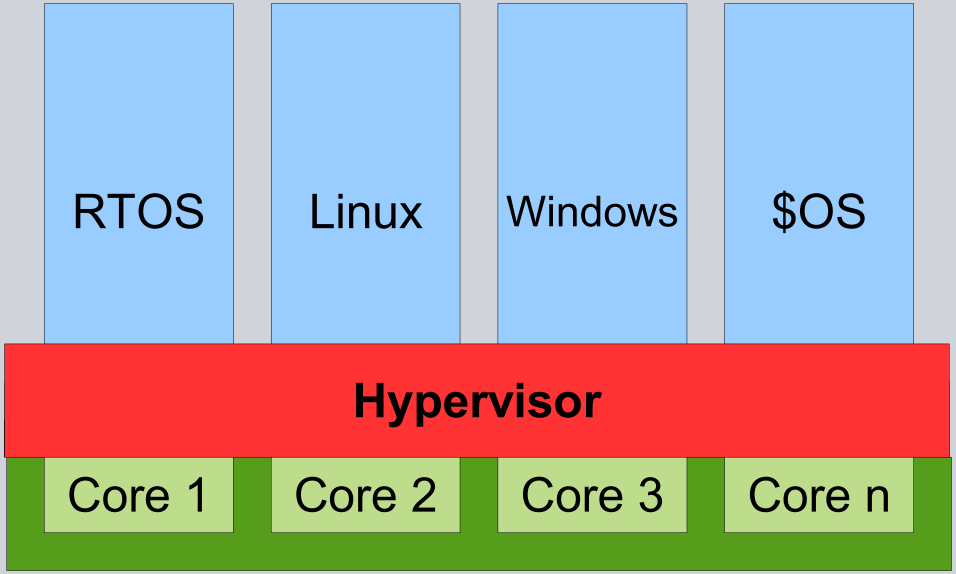
SIEMENS

"We just need a tiny hypervisor to fully exploit this multicore CPU"

- "A few thousand" lines of hypervisor code
- Minimal hardware emulation
- "A bit" paravirtualization
- Devices are passed through

"But it would be nice to..."

- share some devices
- run upstream Linux and latest Windows
- over-commit resources
- manage power



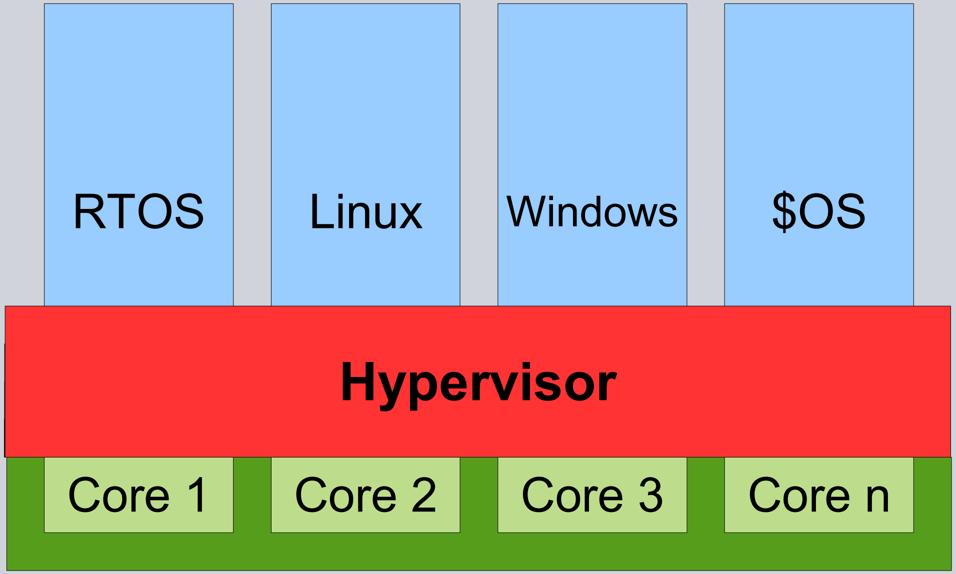
Recall Last Year: Why Using KVM in Embedded?

"We just need a tiny hypervisor to fully exploit this multicore CPU"

- "A few thousand" lines of hypervisor code
- Minimal hardware emulation
- "A bit" paravirtualization
- Devices are passed through

"But it would be nice to..."

- share some devices
- run upstream Linux and latest Windows
- over-commit resources
- manage power
- backup / migrate guests
- use advanced HA features
- ...



...and in Real-Time Scenarios?
Pros & Cons

From partitioning hypervisors...

- \+ High degree of temporal isolation
- \+ Static allocations simplify RT guarantees
- – Poor flexibility
- – Non-commodity setup

...and in Real-Time Scenarios? Pros & Cons

SIEMENS

From partitioning hypervisors...

- \+ High degree of temporal isolation
- \+ Static allocations simplify RT guarantees
- – Poor flexibility
- – Non-commodity setup

... to full virtualization

- – Usually not designed for RT
- – Higher complexity makes establishing RT harder
- \+ Benefit from large user base
  - Guest support
  - Test coverage
- \+ Benefit from advanced virtualization features
- \+ RT and SMP scalability share many requirements

SIEMENS

Typical Real-Time Guest Setups

Guest types

- Classic RTOS
- AMP (RTOS + x)
- GPOS with RT requirements

Guest interacts with real world – in real-time

- Real-time network (normal/RT Ethernet, fieldbuses, etc.)
- Digital & analogue I/O interfaces
- Data acquisition adapters

Interface access

- Pass-through, i.e. 1:1 mapping of periphery to guest
- Emulation
  - Decoupling of guest driver and host hardware
  - Physical interface sharing – or avoiding (test environments)

What is possible today?

Timed Task Benchmarks: Setup (1)

SIEMENS

Host system

- Intel Core i7, 4 cores, 2 threads each
- OpenSUSE 11.4
- PREEMPT-RT kernel 2.6.33.9-rt31
- cyclictest measures timed task wakeup latency

  `cyclictest -n -p 99 -h 500 -q`

- Host-side load
  - Cache benchmark loop

    `calibrator 3392 8M outputfile`

  - I/O benchmark loop

    `echo 1 > /proc/sys/vm/drop_caches ; bonnie -y -s 2000`

- Load loops and cyclictest (for host benchmark) or guest VCPU thread (for guest benchmark) bound to host CPU 0

Timed Task Benchmarks: Setup (2)

Guest system

- OpenSUSE 11.4
- PREEMPT-RT kernel 2.6.33.9-rt31
- qemu-kvm patched to allow prioritization
- VM configured to avoid latency-sensitive guest exits:

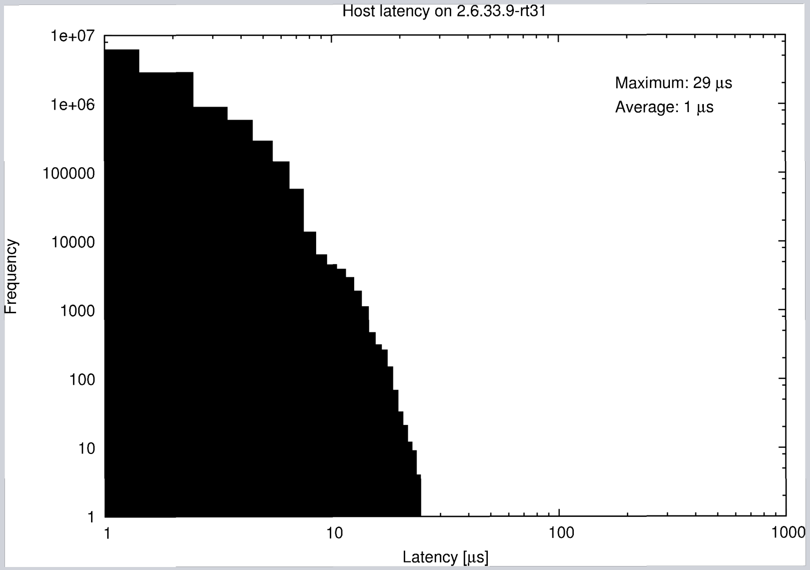
```
-m 1G -drive file=guest.img,if=virtio
-rt maxprio=80,paioprio=1 -nographic -vga none
-netdev user,hostfwd=::2222-:22,id=net
-net nic,netdev=net
```

- cyclictest measures timed guest task wakeup latency

```
cyclictest -n -p 99 -h 500 -q
```

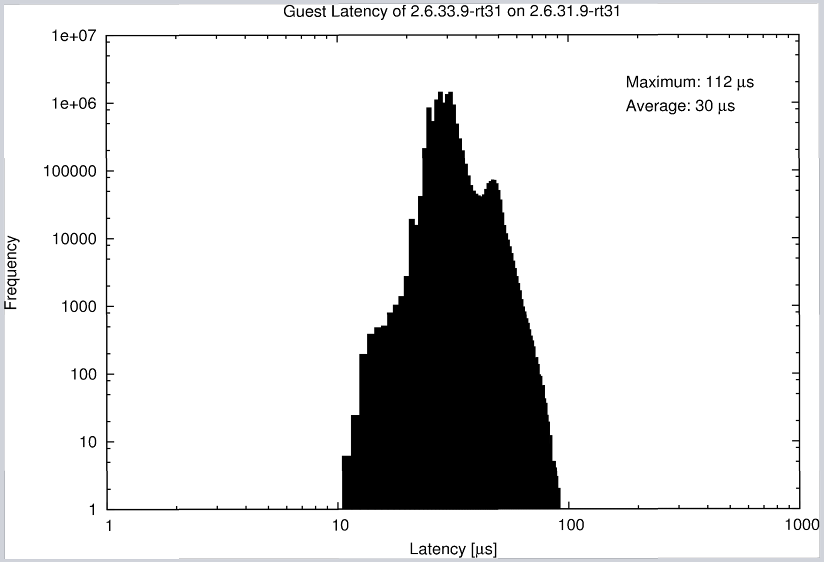
- Host-side load kept unchanged

Timed Task Benchmarks: Results after ~3h



cyclictest on host
Maximum: 29 µs

cyclictest on guest
Maximum: 112 µs



Note: Test length too short for reliable maxima

External Event Benchmark: AMP RT Guest with Passed-Through NIC

SIEMENS

Host configuration

- Base setup as before
- Intel i82541PI NIC as I/O device (no MSI)
- VM with 2 VCPUs

Guest properties

- GPOS and RTOS on different VCPUs
- RTOS only interacts with
  - APIC & IO-APIC
  - Assigned devices (here: PCI NIC)

  => no exits to QEMU user space
- GPOS requires full-blown virtualization, specifically VGA

External Event Benchmark: Measuring Network Latency

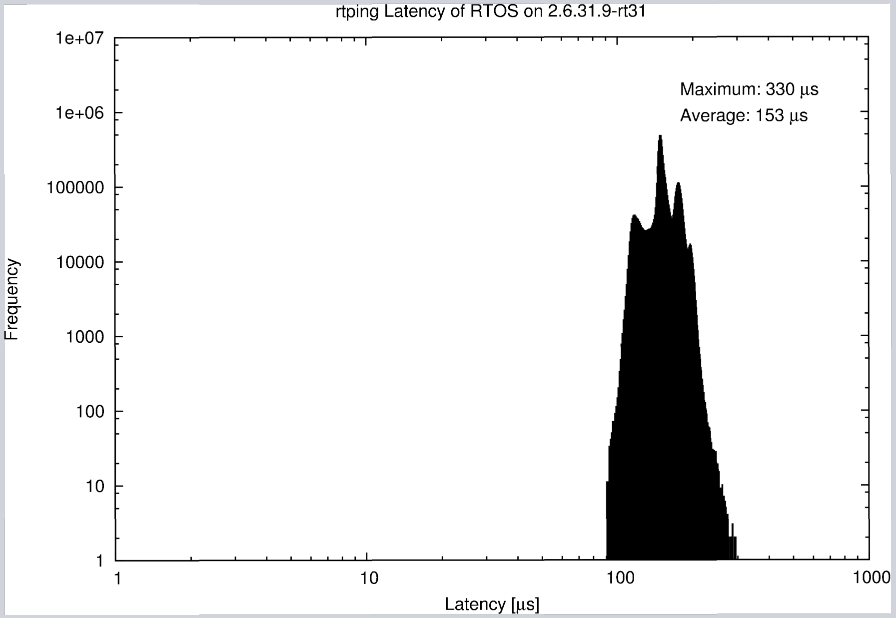
SIEMENS

External measurement system

- Linux/Xenomai with RTnet
- rtping @100 HZ

Load scenario

- `hackbench 150 process 1000`
- Disk I/O load on host
- ping -f from host to GPOS guest (via tap+virtio)
- ftrace enabled for events



Worst case round-trip latency: **330 µs**
(after 16 h)

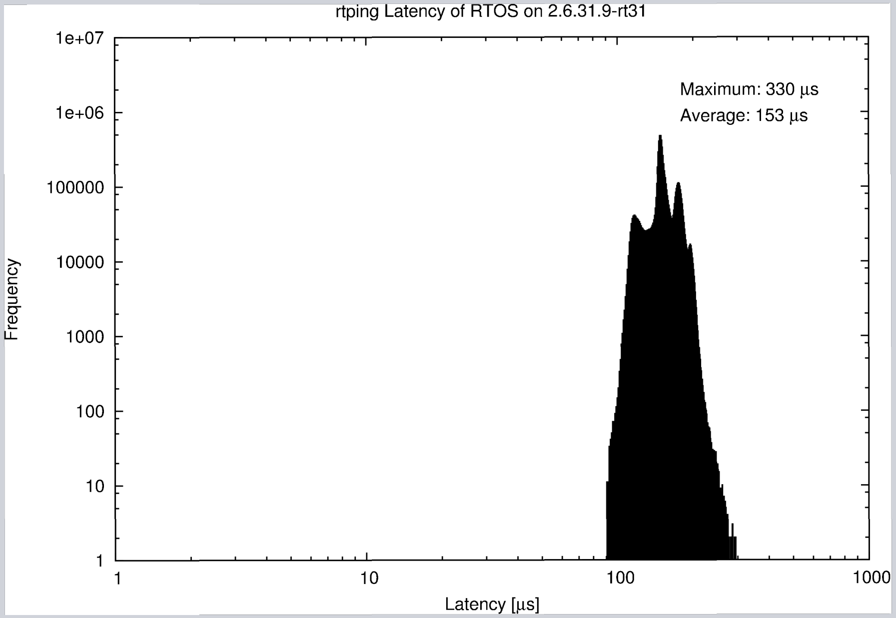
External Event Benchmark: Measuring Network Latency

External measurement system

- Linux/Xenomai with RTnet
- rtping @100 HZ

Load scenario

- `hackbench 150 process 1000`
- Disk I/O load on host
- ping -f from host to GPOS guest (via tap+virtio)
- ftrace enabled for events



Worst case round-trip latency: (after 16 h) — **330 µs**

Same scenario with emulated NIC: (prioritized host NIC IRQ & RX Soft IRQ) — **100 ms – and more**

SIEMENS

QEMU Still Ruining Latencies

Everything under qemu_global_mutex

- Remaining synchronous disk I/O
  *Note: observed io_submit() syscall latencies >1 s,
  paio architecture is immune*
- Network I/O
- Terminal I/O
- X interaction (GUI updates)
- Dirty RAM log synchronization
  (>10 ms on synchronize_srcu_expedited)
- ...and probably more

qemu_global_mutex is a no-go for RT code paths!

Overcoming the Global Lock – Road Works

SIEMENS

CPUState
- Read/write access
- cpu_single_env

PIO/MMIO request-to-device dispatching

Coalesced MMIO flushing

Back-end access
- TX on network layer
- Write to character device
- Timer setup, etc.

Back-end events (iothread jobs)
- Network RX, read from chardev, timer signals, …

IRQ delivery
- Raising/lowering from device model to IRQ chip
- Injection into VCPU (if user space IRQ chips)

Step 1: Localize CPUState

VCPU owns its CPUState

- No remote write unless VCPU is stopped
- Establish formal rule
  (pre-exists for KVM core)
- Just few code changes required

cpu_current_env becomes per-CPU variable

- pthread_set/get_specific on UNIX
- Win32 requires wrapping
- Works with single TCG CPU thread as well

SIEMENS

Step 2: I/O Dispatching

Which device handles accessed memory region?

Critical path

- Walk memory map
- Obtain handler & device reference
- Invoke handler
- Done

Preferred approach: lock-less

- Modifications are rare
- Acquiring read-side lock is costly, may even deadlock

Solution: stop machine while modifying memory map
(pattern also used in kvm-tool)

SIEMENS

Step 3: Coalesced MMIO Handling

Coalesced MMIO ring as contention point

- One ring per-VM
- Readers must synchronize
- Currently protected by qemu_global_mutex

Short-term solution

- Skip flush if target device does not use coalesced MMIO
- Affects VGA and E1000 so far

Long-term solution

- One ring per-device – or MMIO region
- Socket-based ioeventfd may be the answer

Step 4: IRQ Forwarding

Typical IRQ path

- Device changes level / generates edge
- IRQ routers (PCI host, bridges, IRQ remapper, etc.) forward to interrupt controller
- Interrupt controller forwards to CPU

=> **Routing involves** multiple device models,
i.e. potentially **multiple critical sections**

Cannot take the long road if source & sink are in-kernel

- Hacks exist to explore and monitor routes – on x86

=> Generic mechanism required

Fast path from device to target CPU

- No interaction with routing devices
- State changes (reroutes, blockings) reported to subscribers
- Routing device states can be updated on demand

The Harder Nuts –
Step 5: Concurrent Device Models

SIEMENS

Mandatory

- Separate contexts to handle host-originated events
- Enables event prioritization and parallelizing
- iothread(s) can remain “best effort” zone(s)

Variant A

- Per-device lock for atomic sections
- Separate iothreads

Variant B

- Device server thread executes atomic sections

SIEMENS

Variant A: A Lock for Every Device

Per-device lock

- Protects atomic sections (PIO/MMIO requests, event processing)
- Can be taken over VCPU or I/O thread contexts

Separate I/O threads

- Process host-triggered work
  - Device-related file descriptor callbacks
  - Bottom-halves
- Granularity: device or group of devices

Downside

- MMIO addresses device, device issues DMA to another device
  => lock nestings, lock recursions, deadlocks
- Which lock to acquire in which order?
- Can we drop the device lock while calling core services?

SIEMENS

Variant B: Device Server Thread

Server thread runs device jobs

- Host-triggered work
- Complex guest-triggered work

Guest I/O requests forwarded to server

- Write requests can be synchronous and asynchronous
- Reads must be synchronous

Trivial I/O requests do not require server context

- get/set register without side effects

Thread ensures atomicity of device model
=> **no locks required** (famous last words...)

Downsides

- May require careful ordering of state changes
- May require use of atomics & barriers

Work in Progress

QEMU activities

- Implement sketched road map
- Currently focusing on variant B
- Primary target
  - E1000 device model
  - KVM with in-kernel IRQ chips

Kernel activities

- Hunt & analyze potential latency spots (hundred µs range)
- Address IRQ thread management issue

Implementation Footnote: Fun with glibc and POSIX

SIEMENS

glibc's condition variables
+ priority inheritance mutexes
= deadlock

Background

- Internal condvar locks aren't PI-aware
- Using PI locks unconditionally considered too heavy
- Lacking POSIX interface to declare PI for condvars
- Patches exist for pthread_condattr_setprotocol_np
- Ignored by glibc folks :-(

Workarounds

- Use priority ceiling
  - Costly (one syscall per mutex lock/unlock)
  - All participating threads must be SCHED_FIFO/RR
- Don't use condvars

SIEMENS

Summary

Many benefits of using KVM as RT hypervisor

- Full virtualization feature set
- Matured support for broad range of guests

Restricted RT support so far

- Works well without QEMU in the loop
- User space VM exits trigger huge latencies

Ongoing work to reduce restrictions

- Parallelize and prioritize QEMU device models
- Next goal: emulated RT networking
- Event loop latencies $\ll$1 ms in reach

Progress on real-time will improve SMP scalability as well!

Any Questions?

Thank you!
